1. Probability boot camp

(a) Prove Markov's inequality, $Pr[X \ge c] \le E[X]/c$, with c > 0

The formula for the probability of a continuous random variable X with probability density function f(x) is

$$Pr[x_1 \le X \le x_2] = \int_{x_1}^{x_2} f(x)dx$$

And the formula for the expected value of a continuous random variable X with probability density function f(x) is

$$E[x_1 \le X \le x_2] = \int_{x_1}^{x_2} x f(x)$$

so for $Pr[X \ge c]$ we have

$$Pr[X \ge c] = \int_{c}^{\infty} f(x)dx$$

and since X is a nonnegative random variable we have

$$E[X] = \int_0^\infty x f(x) dx$$

Notice that $0 < c \le \infty$. This tells us that the bounds of E[X] are greater than $Pr[X \ge c]$. We can break up the integral formed by E[X] to create an inequality that will begin to look similar to the integral of $Pr[X \ge c]$.

$$E[X] = \int_0^\infty x f(x) dx$$
$$= \int_0^c x f(x) dx + \int_c^\infty x f(x) dx$$
$$\ge \int_c^\infty x f(x) dx$$

We can assume that $x \geq c$ because c is one of the bounds of the integral. This means we can substitute c for x.

$$\int_{c}^{\infty} x f(x) dx \ge \int_{c}^{\infty} c f(x) dx \ge c \int_{c}^{\infty} f(x) dx$$

We now have an equation for E[X] that has $Pr[X \ge c]$.

$$E[X] \ge c \int_{c}^{\infty} f(x) dx = c Pr[X \ge c]$$

Dividing both sides by c gives us

$$E[X]/c \ge Pr[X \ge c]$$

which is Markov's inequality. We have just shown that $Pr[X \ge c] \le E[X]/c$, with c > 0 is true based on the probability and expected value of the continuous random variable X.

(b) Prove Chebyshev's inequality $Pr[|X - \mu| \ge c \cdot \sigma] \le 1/c^2$

If we let $k = (c \cdot \sigma)$ we have

$$Pr[|X - \mu| \ge c \cdot \sigma] = Pr[|X - \mu| \ge k]$$

One of the properties of |a| is that it can also be represented as $\sqrt{a^2}$ so we can change

$$Pr[|X - \mu| \ge k] = Pr[\sqrt{(X - \mu)^2} \ge k]$$

If we take the square root of both sides of the inequality we get

$$Pr[(X - \mu)^2 \ge k^2]$$

From here we can use Markov's inequality since we know $(X - \mu)^2$ is nonnegative. If we let $(X - \mu)^2 = X$ and $k^2 = c$ and substitute those into Markov's inequality we have

$$Pr[(X - \mu)^2 \ge k^2] \le E[(X - \mu)^2]/k$$

The variance σ^2 of a continuous random variable X with mean μ is

$$\sigma^2 = E[(X - \mu)^2]$$

So

$$Pr[(X - \mu)^2 \ge k^2] \le E[(X - \mu)^2]/k$$

Now becomes

$$Pr[(X - \mu)^2 \ge k^2] \le \sigma^2/k$$

If we now change k back to $c \cdot \sigma$ we have the equation

$$Pr[(X - \mu)^2 \ge (c \cdot \sigma)^2] \le \sigma^2/c^2 \cdot \sigma^2$$

Reducing the right side of the equation results in

$$Pr[(X - \mu)^2 \ge (c \cdot \sigma)^2] \le 1/c^2$$

And taking the square root of both sides of the inequality on the left hand side of the equation results in

$$Pr[\sqrt{(X-\mu)^2} \ge c \cdot \sigma] \le 1/c^2$$

Which can be further reduced to

$$Pr[|X - \mu| \ge c \cdot \sigma] \le 1/c^2$$

Which is Chebyshev's inequality. We have just shown that Chebyshev's inequality can be proven using Markov's Inequality.

- (c) Show that for any discrete random variables X, X', E[X] = E[E[X|X']].
- (d) Prove by induction that $E[X_t] = 0$ for a martingale.
